Training systems for drive technology

Technical progress ...

Drive technology is becoming more and more of a force as automation transforms industry. This field is closely intertwined with other areas of technology like process automation, automatic control technology or computer technology. Due to the rapid pace of developments here, drive technology has become one of the most innovative areas of electrical engineering.

... is having an enormous impact on training and education

New industrial drive technologies are necessitating new training systems. New developments like the proliferation of frequency converters and servo drives as well as their integration in process automation systems are only a few examples of how fields in vocational studies are being transformed. This increases the demands on today's drive technicians which leads in turn to a need for modern, practice-oriented training systems that are capable of training students on the latest state-of-the-art technology and how to competently handle such equipment.

A strong partner in industry ...

... is the guarantee that our systems are closely modelled to actual practice. Lucas-Nülle has found this strong partner in the highly rated drive technology producer Lenze AG. First, we take the most state-of-the-art drive technology products manufactured by Lenze and modify them for teaching purposes by precisely adapting them to the needs of training schools and educational institutions. All power stages are covered, ranging from simple motor controls to frequency converters up to and including servo converters with field-bus interfaces for integration into process automation.

AC Machines

Single-phase motor with bifilar starter winding

The single-phase motor with bifilar starter winding is one of the asynchronous machines. In addition to the main winding, there is a starter winding which has a high internal resistance which is partially bifilar and thus magnetically ineffective. This is disconnected after starting is achieved. The motors do not contain any parts which would be subject to wear and tear like a collector or slip-rings, and operate at a fixed, virtually synchronous speed. The power range reaches up to approx. 2 kW.

Experiment example: "Single phase motor with bifilar starter winding EEM 3.3"

- Reversal of rotation direction
- Recording the speed and torque response
- Operation with different load machines, like ventilators

Single-phase motor with operating and starting capacitor

Single-phase motors with operating and starting capacitors belong to the cadre of asynchronous machines. Besides the main winding, these motors are equipped with an auxiliary winding with a series-connected capacitor. The motors do not contain any components which are subject to wear and tear like collectors and slip-rings and operate at a fixed and virtually synchronous rotation speed. The power range reaches up to approximately 2 kW. Capacitor motors are used to drive household appliances, refrigerators as well as small-scale drives used in manufacturing machinery.

AC Machines

Split-pole motors

Split-pole motors excel due to the fact that they are cost-efficient to produce and practically maintenance-free. Split-pole motors are constructed especially for deployment in mass-produced devices like ventilator motors or discharge pumps. The power range stretches from a few watts up to a power level of approx. 150 W.

Experiment example: "Split-pole motor EEM 3.5"

Asynchronous Machines

Three-phase motors with squirrel-cage rotor

Three-phase motors with squirrel-cage rotors are the most frequently used motors in industry. These motors are not only both robust as well as maintenance-free but are also inexpensive to produce. The motors can be found in low-power versions in the watt ranges up to and including power levels of several megawatts. Thanks to the use of modern frequency converters, these motors can operate virtually loss-free at varied speeds enabling ever-more application areas to be found for them.

Asynchronous Machines

Three-phase, pole-switchable motor according to Dahlander

Due to the special winding, the three-phase motor with a Dahlander circuit enables the three-phase motor to be operated at two different speeds. The ratio of the speeds for this circuit is 2:1. With this type of motor simple drives can be assembled that are capable of two speeds, for example, a two-staged ventilator drive.

Experiment example: "Three-phase, pole-switchable motor according to Dahlander EEM 4.2"

- Operation with high- and low-speed stages
- Using a pole-reversing switch
- Recording speed and torque characteristics
- Operation with different load machines such as ventilators, hoisting equipment

Three-phase pole-changing motor – two separate windings

The system consists of two three-phase motors in a single housing with separate windings. Since both windings operate separately from each other, different integer ratios can be produced between the speeds. These motors are always used for simple applications wherever the speed ratio between slower and faster speed is greater than two, for example, in crane applications where you have inching mode and higher speed.

Experiment example: "Three-phase pole-switchable motor with two separate windings EEM 4.3"

- Operation at higher and lower rotation speeds
- Using a pole-reversing switch
- Recording speed and torque characteristics
- Operation with different load machines such as ventilators, hoisting equipment

Asynchronous Machines

Three-phase motor with slip-rings

In contrast to motors with squirrel-cages, slip-ring motors are equipped with a rotor outfitted with wound coils. These rotors can be connected to resistors or static converters. This makes speed adjustment possible.

- Connecting, wiring and putting into operation
- Adjusting the speed by altering resistance across the rotor
- Recording speed and torque characteristics
- Operation with various load machines such as ventilators, hoisting equipment

These faults can be detected and analysed using industrial-type measuring instruments. Repair measures can be worked out on the basis of the measuring results. All measurements are performed with the power switched off.

Equipment Set: EEM 4.5 Lucas-Nülle

Asynchronous Machines

Protection for electrical machines

Squirrel-cage motors were designed to operate with constant loads. Load changes as well as high start-up currents lead to excessive overheating of the motor. Sensors are used to monitor the temperature and the motor's current consumption. These activate protective devices such as motor circuit-breakers, protective relays or thermistor relays.

The development of circuits as well as the correct choice of circuit elements and equipment is at the focal point of this training system segment. Multi-poled motors up to a certain power class can be switched directly into the three-phase circuit. To do this, appropriate switching equipment is provided for each application.

This is why indirect switching is performed on these machines using contactor circuits of various kinds. The training here features the development of control circuitry and how operational control is designed. Using the extension equipment sets, it is possible to explore even more complex control operations and tasks. The machine equipment set contains all of the motors and equipment required to test direct and indirect control of motors in the three-phase circuit.

Synchronous/Reluctance Machines

Synchronous motors and generators

Synchronous machines are primarily used as generators in power supply networks. Power levels in this area can reach up to around 2,000 MVA. Other additional areas of application are large-scale drives for cement mills and conveyor belt systems with power levels in the megawatt range. Highly dynamic servos with permanently excited rotors complete the spectrum of synchronous machines. In contrast to asynchronous machines, here the rotor operates in sync with the rotating magnetic field.

Equipment Set: EEM 5.1 Lucas-Nülle

Synchronous/Reluctance Machines

Mains synchronisation

In the case of mains synchronisation, the unloaded generator is switched to the mains. Voltage, frequency and phase angle have to coincide with the corresponding variables on the mains. Different measuring instruments are used to measure these variables. The variables are set by means of the generator speed and excitation.

Experiment example: "Mains synchronisation EEM 5.2"

- Manual mains synchronisation with the aid of synchronising bright-method, dark-method and three-lamp synchronisation circuits
- Mains synchronisation using two-range frequency, two-range voltmeter, synchronoscope and zero-voltage meter
- Influence of the generator speed
- Influence of generator excitation
- Adjusting power flow by means of the drive

Three-phase reluctance machine

Reluctance motors constitute a cross between asynchronous and synchronous motors. Due to the special design of the rotor with salient pole construction, the motor is able to operate like an asynchronous motor. Starting at a certain speed, it then locks into synchronous speed with the stator field. Reluctance machines are used, for example, in the textile industry for synchronous despooling of yarn. This involves several motors operating under the control of a frequency converter.

Experiment example: "Three-phase reluctance machine EEM 5.3"

Power Electronics and Didactically Designed Drives

Loss-free control of electrical machines

Power electronics is the technology of switching and converting electrical power to greater power levels. Nowadays we use power semiconductors like diodes, thyristors and IGBTs to perform these operations. The main application area for power electronics is drive technology.

The training systems in this area are designed to explore technical relationships beginning with static converter technology and even include automatically controlled drives. The software is well-conceived and provides the consistent support crucial for both quick and clear experiment set-up and rapid learning success.

Power semiconductors

The rapid developments being made in power semiconductors continue to forge ever-newer applications and improvements in electrical drives. Innovations include the following: shrinking power loss, work with higher frequencies and operation with "intelligent power modules".

These modules contain, in addition to power semiconductors, the control unit and safety circuitry needed to protect against impermissibly high currents and excess temperatures.

Automatic control of machines

Many manufacturing processes employ automatic speed-controlled drives or positioning drives. Besides the machine and its associated power electronics, it is the automatic control system which exerts a great deal of influence on the drive's response. It is the technician's job to make sure that control operation is suited to the manu-facturing process.

Training systems

Our training systems cover the following topics:

- Line-commutated static converters
- Self-commutated static converters
- Automatically controlled DC drives
- Frequency converter drives

Line-commutated Power Converters

Uncontrolled rectifiers – controlled rectifiers – AC and three-phase AC power controllers

Power electronics is firmly anchored in modern life. Otherwise such things as dimmable halogen lighting, speed-variable drills or electric heating would be impossible. Power semiconductors such as diodes, thyristors and power transistors make all this possible.

- Design and operation of single-phase and three-phase rectifiers
- Operating characteristics of uncontrolled, semi-controlled and fully controlled static converter circuits
- Power semiconductors and their control
- Power electronics measurement variables

- Analysis of current, voltage and power using fast Fourier transform analysis (FFT)

Self-commutated Power Converters

PWM – four-quadrant power controller – power inverter

The number of speed-variable drives to be found in modern machines is constantly increasing. The reasons for this are the growing expectations and the advent of modern competitively priced power inverters. Today these power inverters work with PWM technology.

- Recording control and operating characteristics
- Design and operation of three-phase AC inverters
- Block commutation, sinusoidal, super-sine and space vector modulation for the generation of voltage- and frequency-variable voltages
- Instrumentation-based analysis of various modulation methods based on signal characteristic measurements and fast Fourier transform analysis (FFT)

Frequency Converter Drives

- Generation of DC link voltages
- Recording U/f-characteristics

- Recording and analysing currents, voltages and power levels

Active Power Factor Correction PFC

Active PFC control – harmonic analysis

Today, every mains power supply built into a computer is equipped with PFC (PFC – Power Factor Correction). The reason for this popularity is a European-wide norm that stipulates that, as of a particular power level, loads have to draw their current from the mains in a linear relationship to their voltage characteristic.

- Design and operation of an active power factor correction circuit
- Application areas for power factor correction
- Comparison to conventional bridge rectifier circuits
- Recording and analysing currents, voltage and power levels (also using FFT)

Speed Control of a Three-phase Asynchronous Motor

Slip control – smooth starting

Three-phase asynchronous motors with squirrel-cages are the machines most commonly put to use in industry. Frequency converters allow for the open-loop control of machines. Slip control is an alternative made possible by phase-angle control. This kind of control is frequently implemented in so-called smooth-starting machinery. During start-up, phase-angle control is used to reduce the effective voltage so that the motor can be switched into the mains without being subjected to high switch-on currents. As a rule, smooth-starting machines replace the star-delta circuit starting.

Industrial Drives

Parameterization of industrial components

Today, the idea of a modern industrial world without controllable electrical drives is totally unthinkable. Their area of application ranges from high power performance to traction drives, machine tools and production machines up to and including applications in the automotive sector. As opposed to didactically designed drives, these training systems are equipped with industrial equipment. The training here focuses on how to handle and set the parameters of real industrial drive equipment.

Industrial components

The use of industrial components made by well-known manufacturers such as Lenze AG or Siemens puts us in a position to convey practical industrial know-how directly to the student. The designations of all of the terminals and connections correspond exactly to equipment used in industry. Standard industrial operating instructions and software are used in the projects and exercises.

Multi-disciplinary

Field-bus interfaces in connection with frequency converters, servo drives and motor management relays provide the basis for interdisciplinary applications together with automation technology. The drives can be controlled via PLC and operated using HMIs. This permits the visualisation of typical process control variables, disturbance variables and operating modules.

Training systems

Our training systems cover the following topics:

- Smooth starters
- Frequency converter drives
- Servo drives
- Motor management relays

Smooth starting Three-phase Machines

Cutting high switch-on currents

Smooth starters use phase-angle control to reduce the motor's voltage during switch-on. The starting current drops proportionally to the terminal voltage. The power section of a smooth starter normally consists of two thyristors switched anti-parallel per phase. In order to be able to keep the power losses and the associated heat build-up as low as possible, the power semiconductors are shunted by a power circuit-breaker subsequent to the starting phase.

- Setting the parameters for run-up, run-down and starting voltage
- Examining the current and voltage levels during starting
- Starting under different load scenarios

Frequency Converter Drives

The variable speed drive

Modern frequency converters transform any given three-phase standard motor into a drive with variable speed. The robust nature and popularity of three-phase standard motors have made a significant contribution to the huge success that electronic drive technology with frequency converters enjoys. The higher demands placed on drives due to developments in process automation means that more and more motors are being controlled by frequency converters. Thanks to customised open-loop speed control, today pumps and air-conditioning units are able to save a substantial amount of energy.

Positioning with Synchronous Servo Drives

Always the right position

When people talk about servo drives today, they generally mean highly dynamic three-phase drives. Servo drives primarily perform positioning tasks in tooling machines, manipulators or robots. But these devices are increasingly finding their way into printing machines, conveyor belts and cutting machinery where precise positioning or angular synchronism are required. Here, servo converters, motors with sensor technology and mechanical transfer elements form an extremely integrated system whose components have to be seen as a single entity.

Motor Management Relays

Effective motor protection – preventive maintenance

Motor management systems are put into action in modern automation systems and make it possible to provide drives and processing systems with the optimum protection, control and monitoring system. These systems permit the detection of, for example, the motor temperature, voltage or current. The transparency of the motor and its functions is enhanced thanks to the field-bus system (e.g. PROFIBUS) that connects it to the primary process automation system. Consequently, the motor's operating capacity and energy consumption can be determined without having to perform measurements on site.

Decisive Product Benefits

... provide customers with long-term satisfaction

Mr Georg Greshake, Teacher at Heinz-Nixdorf-Berufskolleg (Vocational College) in Essen:

"As always, the Lucas-Nülle training systems for drive technology just thrill me", says Georg Greshake, a teacher at Heinz-Nixdorf-Berufskolleg in Essen, "I have been using the servo machine test stand for many years now in mechatronics studies and I'm always completely satisfied with how the equipment performs during instruction.

Only just recently we upgraded and refurbished our vocational college laboratories and workshops with training equipment from Lucas-Nülle. We were impressed by the systems' high quality, didactically sound design and practice-tested conceptualisation.

By implementing the entire program, I can systematically plan out the entire training program, including the deliberate and careful introduction of industrial applications. The modular design of the system is one proven and integral feature.

The UniTrain-I system is used by the students to explore the important fundamentals. After this, they move on to the training panel system. The servo and machine test stand provides for impressive and realistic simulation of the industrial standard for instructional purposes.

It provides a true-to-life simulation of a wide range of different load machines. Even motor run-up experiments can be performed independently by the students. This enables them to reach a very high level of learning in a very short time and makes experimenting on one's own easier.

Ultimately our students are able to take the experience they gain during instruction and transfer it wholesale into hands-on work performed in true-to-life conditions in the training centre."
